Why body condition score your herd?

Assessing a cow’s BCS using a 1 to 8 scale provides a standardised measure of a cow’s energy (and protein) reserves, and tells a lot about:

- previous level of feeding,
- likely future productivity, and
- future feed requirements.

Effective management of body condition and nutrition improves herd reproductive performance, milk production, feed conversion efficiency, and enhances cow health and welfare.

Cows that are too thin at calving are less fertile and produce less milk

- They take longer to recommence cycling, reducing submission rates and conception rates.
- They partition more feed energy to body condition gain versus milk production. This means cows fail to achieve their genetic peak milk yield and have lower lactation persistency.

Cows that are too fat at calving often have health problems

- They are more likely to have calving problems, metabolic disorders and other health problems, and have poorer appetites after calving than thinner cows.

Cows that lose excessive condition in early lactation are also less fertile

- They take longer to recommence cycling, reducing submission rates and conception rates. Poor expression of heat signs can also occur.

Measuring and managing body condition is all about managing your herd’s nutrition program. Condition scoring your cows at critical times during their lactation cycle lets you know if you need to consider changing herd nutrition.
What is body condition scoring?

Body condition scoring is a visual assessment of the amount of fat and muscle covering the bones of a cow, regardless of body size. It is not affected by gut fill or pregnancy as liveweight is. It involves assessing specific locations on the cow to determine how thin or fat the cow is.

The 1 to 8 body condition scale

Different systems are used to body condition score dairy cattle and beef cattle. In Australia, an 8 point scale is most commonly used for dairy cattle:

- A cow with a BCS of 1 is considered extremely thin, the result either of severe under-feeding or disease.
- A cow with a BCS of 8 is considered extremely fat and is at risk of several metabolic diseases after calving.

Body condition scoring using this 8 point scale provides a quick, easy, consistent way to assess body condition in dairy cattle. Only cows with a BCS of 3 to 6 are shown in this booklet as healthy, productive cows in commercial dairy herds should always be within this range.

The scoring method is the same for all dairy breeds despite their differences.

<table>
<thead>
<tr>
<th>Holstein-Friesians</th>
<th>Angular body shape, appear thinner, carry more body fat over ribs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cross-breds</td>
<td>More even distribution of fat over body</td>
</tr>
<tr>
<td>Jerseys</td>
<td>Narrow body with prominent hip bones and higher set tail</td>
</tr>
</tbody>
</table>

Note: Other dairy body condition scoring systems use different scales eg. 5 point (US and Ireland), 10 point (New Zealand).
Body condition targets

A herd’s range in body condition score (BCS) is as important as its average BCS. We need to know what proportion of cows are too thin and too fat, as these cows are likely to have reduced reproductive performance and milk production, and increased risk to their health and welfare.

Targets

At calving:

– No more than 15% of cows below BCS 4.5.
– No more than 15% of cows above BCS 5.5.

At mating:

– The decrease in average BCS of the herd since calving is no more than 0.6.
– No more than 15% of cows lose more than one BCS since calving.
– Cows maintain or gain body condition from commencement of mating.
  (see page 36 for benefits from achieving BCS targets)

At drying-off:

– Cows in desired condition score at calving.
– Cows maintain or gain body condition during the dry period.
How to body condition score a cow

2-step “hands-off” scoring method only takes seconds

Using the scoring method described in this booklet is simple and it only takes seconds to score each cow. You only need to make two observations to determine the BCS of any cow to the nearest half score.

– The first observation is made from the back of the cow, focusing on a location where it is easiest to see that she is starting to lay down fat.

– The first observation determines which part of the cow’s body to focus on next. The second observation may be the area between the tail and pins, the backbone or the depression between the hip and pin.

This method is “hands off”. It can be done from a distance. However, to get your eye in, it is a good idea to score some cows “hands on” (see page 17).

Don’t agonise over each cow’s BCS. Make a quick assessment and move on to the next cow. If you score the recommended number of cows (see page 20), the cows you scored a little generously or harshly will balance each other and you will get a good indication of the herd’s average BCS and the range of scores within the herd.
Key points to look at

1st Observation

Look closely at area between tail and pins:
Is it deeply sunken, sunken, slightly sunken or filled in?

2nd Observation

If area between tail and pins is deeply sunken:
Look at insides of pins. Are they hollow?

If area between tail and pins is sunken:
Look at backbone. Is it flat or a bumpy sharp ridge?

If area between tail and pins is slightly sunken or filled in:
Look at depression between hip and pin. Is it U-shaped, shallow or flat?
How to body condition score a cow

1st Observation

How sunken is the area between the tail and pins?

- Deeply Sunken
- Sunken

2nd Observation

- Are the insides of the pins hollow?
  - YES
  - NO

- Is the backbone a bumpy sharp ridge?
  - YES
  - NO

Condition Score
- Condition Score 3
- Condition Score 3.5
- Condition Score 4
- Condition Score 4.5
The depression between the hip and pin is:

- Slightly Sunken
- Filled In

U-SHAPED
- Condition Score 5

SHALLOW
- Condition Score 5.5

FLAT
- Condition Score 6
Condition Score 3 All breeds

1st observation
Area between tail and pins is deeply sunken

2nd observation
Insides of pins are hollow

Cows in this score also have:
- Very prominent hips
- A backbone that is a very bumpy ridge
Condition Score 3.5  All breeds

1st observation
Area between tail and pins is deeply sunken

2nd observation
Insides of pins are not hollow

Cows in this score also have:
- Prominent hips
- A backbone that is a bumpy ridge

**Condition Score 6** All breeds

1st observation
Area between tail and pins is filled in

2nd observation
Depression between hip and pin is flat
Get your eye in first

Body condition scoring is easy. However, if you are not very experienced or are a little out of practice, it is a good idea to calibrate your eye first by condition scoring some cows ‘hands on’. The ideal place to do this is an AI race.

– Line up 10 cows with a range of body condition.
– Put your hands on the key points of each cow—the area between the tail and pins, the backbone and the depression between hip and pin.
– Feel the amount of fat cover over these body points and the differences between the cows.
– Score each cow using the method described on pages 8 and 9.

Now you are ready to condition score your herd using the ‘hands off’ method in the paddock or the dairy.

Body condition scoring your herd (cont)

How many cows to score?

It is very important to score a representative selection of cows in your herd.

Seasonal/split calving herds

- Score 70 cows each time.
- Even in large herds, 70 cows is sufficient each time.
- It is not necessary to score the same cows each time.
- Record each score separately; record cow identity if you wish.
- With practice, scoring 70 cows should take no more than 30 minutes.

Year-round calving herds

- If you are milking fewer than 300 cows, you will need to score all cows at drying-off, just before calving and when they become eligible for insemination.
- At 450 cows, scoring two out of every three cows should be sufficient.
- At 600 cows, scoring every second cow should be sufficient.

Where to score cows?

Cows are most easily scored in the paddock or in the dairy at milking.

In the paddock:

- Walk through the herd, scoring cows as you go.
- Position yourself within 20–30 metres of the cows.
- Score cows when they are standing with their tail, rump and back clearly visible.
In the dairy at milking:

**Rotary:**
- Look at cows from a position above and to the rear of them using a raised platform close to the cows.
- Ensure lighting is adequate.
- Select cows based strictly on where they are milked. For example: mark every 8th bail on the platform.
- Don’t score the first or last 70 cows to be milked.

**Herringbone:**
- It is not possible to score cows accurately from the pit.
- Step up to view selected cows from above and to the rear.
- Select cows based strictly on where they are milked. For example: mark every 4th set of cups and score cows in those positions only.
- Don’t just score the first or last 70 cows to be milked, or the first or last cow in on each side to be milked.
- Alternatively, score cows in the exit race as they leave the dairy.
Recording body condition scores

Using recording sheets

Here is an example of a BCS recording sheet which enables you to calculate the average BCS of your herd and the all important percentages of thin and fat cows (i.e. those below 4.5 and above 5.5).

To download blank copies of recording sheets, go to www.dairyaustralia.com.au/BCS
Using smartphone app

Alternatively, if you have an iPhone or Android smartphone, you can download Dairy Australia’s free BCS app and use it to condition score your herd and compare results to the BCS targets.

To download the app, go to:
What if results are off target?

Seasonal/split calving herds

1. At 8–10 weeks before drying-off

<table>
<thead>
<tr>
<th>BCS results</th>
<th>Immediately</th>
</tr>
</thead>
</table>
| More than 15% of cows are below BCS 4.5         | If possible, increase feed inputs to increase body condition in late lactation. Target all cows or just cows below score 4.5 if you can preferentially feed. Do a cost:benefit analysis before considering these options:  
  – Early dry-off for cows below score 4.5 in late lactation.  
  – Once-a-day milking in mid-late lactation. Then, feed to maintain or increase condition during dry period. |
| More than 15% of cows are above BCS 5.5         | Feed to maintain condition during dry period. Don’t allow over-conditioned cows to lose condition when dry. |
What if results are off target?

Seasonal/split calving herds

1. At 8–10 weeks before drying-off

**ACTIONS TO CONSIDER**

- **BCS results** Immediately

  To prevent it happening again

- More than 15% of cows are below BCS 4.5

  If possible, increase feed inputs to increase body condition in late lactation. Target all cows or just cows below score 4.5 if you can preferentially feed.

  Do a cost:benefit analysis before considering these options:
  - Early dry-off for cows below score 4.5 in late lactation.
  - Once-a-day milking in mid-late lactation. Then, feed to maintain or increase condition during dry period.

- Seek help from an adviser to:
  - Examine the costs and benefits of increasing feed inputs during mid-late lactation.
  - Determine if reducing stocking rate is appropriate.

Check that all cows have equal access to feed.

If most thin cows are first calvers, then review management of heifers.

- More than 15% of cows are above BCS 5.5

  Feed to maintain condition during dry period.

  Don't allow over-conditioned cows to lose condition when dry.

- Seek help from an adviser to:
  - Check diet fed throughout lactation if most fat cows have been calved less than 10–12 months.
  - Determine if cows are being overfed in mid-late lactation.

If most fat cows are carryover cows, then improvements to herd reproductive performance will reduce this problem in the future.

**Additional energy inputs needed for BCS gains**

It takes more feed energy inputs to put on a condition score when a cow is dry than when she is lactating because energy is used less efficiently during the dry period. Every kg of body weight gain requires about 42 Megajoules Metabolisable Energy (MJ ME) in a lactating cow and 58 MJ ME in a dry cow.

Bigger cows need more MJ ME to put on a condition score, and this energy input increases as BCS increases.

<table>
<thead>
<tr>
<th>Cow’s liveweight</th>

<tr>
<td>750 kg (Large framed Holstein-Friesian)</td>
<td>91</td>
</tr>
</tbody>
</table>

(Source: CSIRO (2007). Nutrient requirements of domesticated ruminants)
Example:

If you wanted to put half a condition score on your 550kg Holstein-Friesian lactating cows in the last 45 days before drying-off, you would need to feed each of them an additional 23 megajoules of metabolisable energy per day.

If feeding a concentrate with an energy density of 11.5 MJ ME / kg DM, you would therefore need to feed each cow an extra 2 kg DM extra (or 2.2kg as fed of extra concentrate @90%DM).

Use energy/protein dense supplements to provide the extra energy within the cow’s daily food intake limits.

Seek help from an adviser to design a balanced diet for the desired BCS gain.
Benefits from achieving BCS targets

Reproductive performance

Cows that calve in the BCS range 4.5–5.5 have 6-week or 100-day in-calf rates at least 12% higher than if they had calved at a BCS below 4.5.

– If you actually had 35% of cows in your herd below BCS 4.5 and 20% above BCS 5.5, the impact on 6-week/100-day in-calf rate would be about 5%. If you achieved a more desirable profile with 10% of cows in the herd below BCS 4.5 and 5% above BCS 5.5, the herd’s potential improvement in 6-week/100-day in-calf rate would be 4%.

– Cows that lose less than one condition score between calving and mating have higher in-calf rates compared to cows with greater losses.

– A reduction from a 0.75–1.0 to a 0.45–0.6 average herd BCS change in early lactation is likely to have the following beneficial effects:
  • 3% higher 6-week/100-day in-calf rate
  • 2% lower Not-in-calf rate

Milk production

Cows that calve in higher body condition score have more body fat (and protein) reserves which they can mobilise in early lactation to support milk yield. However they tend to have reduced appetites, and take longer following peak milk yield to reach maximum feed intake than thinner cows.

Research studies indicate that when a herd is offered ad lib feed of high quality, thinner cows can take advantage of their increased appetites in early lactation, and produce as much or even more milk as their fatter herd mates. However, if feed quality is sub-optimal and/or access to feed is restricted (as it often is in pasture-based systems) then thinner cows will produce less milk than their fatter herd mates.
If you still have questions about measuring and managing your herd’s body condition, here’s where to go for further information and support:

This webpage contains a number of resources related to herd body condition and nutrition, including:

– BCS recording sheets.
– BCS smartphone app.
– More information on aspects of managing body condition and nutrition.

An adviser can assist you with evaluating your herd’s performance and help develop strategies for your situation.
